

# Credible on Paper? Green Banking Policy, Access to Finance, and Institutional Capacity in the Greening of Firms Worldwide

Anonymous for review

---

## Abstract

Green banking policy frameworks coordinated through the Sustainable Banking and Finance Network (SBFN) have been adopted across more than sixty emerging and developing economies since 2012, on the premise that supervisory guidelines directing banks to price environmental risk into lending will strengthen the link between firms' access to credit and their green investment behaviour. We test this premise using two independent World Bank Enterprise Survey samples. The primary sample harmonizes the Bank's full 2018–2020 Green Economy Module rollout across 41 economies (28,042 firms) on a rich seven-item green-practice-adoption outcome, matched to each economy's SBFN policy-adoption status and Worldwide Governance Indicators regulatory quality as of its survey year. Because SBFN status is fixed within country in a single-wave cross-section, a classical country-fixed-effects specification cannot identify it or its interactions; we show this explicitly, then re-estimate the relationship with a Bayesian hierarchical model (country-varying slopes) and a causal forest that impose no linear-interaction functional form. All three approaches agree: bank credit access is robustly associated with green practice adoption (average marginal effect of 13 percentage points in

the baseline specification), but neither SBFN policy adoption nor regulatory quality moderates it—both institutional variables instead shift the general level of green adoption directly. We then subject this finding to the sharpest test we can construct: a second, independently assembled sample of 162 further economies (89,797–100,115 firms depending on specification), spanning 2021–2026 and reaching, for the first time in this literature, into high-income economies such as Australia, Germany, and Japan, built from a World Bank standardized cross-country database not previously exploited for this purpose. On a narrower CO<sub>2</sub>-emissions-monitoring outcome and with country fixed effects the primary sample’s single-wave design cannot support, credit access remains significant while both SBFN and regulatory-quality interactions remain statistically indistinguishable from zero—the identical qualitative pattern, on a different outcome, a different set of economies, and a materially sharper identification strategy. The causal forest’s feature-importance decomposition attributes the bulk of genuine effect heterogeneity in the primary sample (75.6%) to firm size rather than to either institutional moderator (regulatory quality 19.9%; SBFN status 2.6%). One finance-instrument-specific check finds a nominally significant negative credit  $\times$  SBFN interaction when finance access is measured via overdraft rather than term credit, though this does not survive a Benjamini–Hochberg correction for multiple comparisons across the full family of interaction tests reported in the paper, and we treat it as suggestive rather than established. We interpret the combined evidence as more consistent with green banking policy’s binding constraint operating through firm-level absorptive capacity than through the country-level regulatory capacity its own institutional design targets, though

we report this as our best current account of an auxiliary, exploratory finding rather than as a settled result.

## 1. Introduction

Since 2012, more than sixty central banks, banking regulators, and financial-sector regulatory bodies across the emerging and transition world have signed on to a coordinated effort to green their financial systems, adopting national guidelines that direct commercial banks to price environmental and climate risk into lending decisions and to channel credit toward cleaner production. On paper, this represents one of the most ambitious diffusions of environmental financial regulation outside the OECD: economies as different in income, banking-sector depth, and political regime as Bangladesh, Morocco, Mongolia, and Indonesia now report, to the International Finance Corporation’s Sustainable Banking and Finance Network (SBFN), formal sustainable-finance roadmaps, green-taxonomy pilots, or mandatory environmental-risk disclosure rules for lenders. Whether that adoption changes what actually happens on a factory floor—whether a firm that can get a bank loan is any more likely to install a wastewater treatment system, switch to a more efficient boiler, or measure its own emissions—is a separate and considerably harder question, and it is the one this paper answers.

The premise that formal adoption of a policy is not the same as its op-

eration in practice is, of course, not new to institutional economics. A large literature on state capacity and policy credibility has long argued that the same law, regulation, or guideline can produce entirely different real-economy outcomes depending on the administrative and judicial infrastructure available to enforce it (La Porta et al., 1998; Acemoglu et al., 2001). Applied to green finance specifically, a parallel body of work has documented that green credit guidelines in China measurably reshape lending allocation and firm environmental performance (Li et al., 2023; Huang et al., 2023; Dai et al., 2025), that firms’ green investment responds to the financing constraints they face (Ghosh and Dutta, 2022; Costa et al., 2024; De Haas et al., 2025), and that the World Bank Enterprise Surveys’ own Green Economy module is a workable lens on firm-level environmental behaviour across dozens of countries at once (Asif et al., 2025; Phan, 2026). What is missing is the connection between these two literatures: a direct test, at firm level and across a wide cross-section of the very economies the green-banking-policy movement targets, of whether the credit-to-green-investment channel that these guidelines are designed to activate is actually stronger where the guidelines exist—and whether that depends on the state capacity to make the guideline credible in the first place.

This paper closes that gap using firm-level data from two independently assembled samples of World Bank Enterprise Survey (WBES) waves. The primary sample covers 47 country-years fielded between 2018 and 2023 that carry the Bank’s full Green Economy module—a battery of questions on emissions monitoring, energy audits, and the adoption of climate-friendly production measures—alongside the Surveys’ standard access-to-finance module; a

44 second, global sample extends this to 162 further country-years fielded be-  
 45 tween 2021 and 2026, reaching for the first time in this literature into high-  
 46 income economies with no SBFN involvement at all (Section 4). We match  
 47 each economy to its Sustainable Banking and Finance Network policy status  
 48 as of its survey year, distinguishing genuine ex-ante policy adopters from  
 49 economies that joined only afterward, and to the World Bank’s Worldwide  
 50 Governance Indicators as a measure of the regulatory state capacity avail-  
 51 able to make that policy credible. Econometrically, we depart deliberately  
 52 from the pooled fixed-effects specification that has become the default in  
 53 this literature. Because SBFN status is fixed within country in a single-wave  
 54 cross-section, a country fixed effect absorbs it entirely, and a naive interaction  
 55 term estimated by pooled logit—which we report first, as a baseline, precisely  
 56 to make this limitation visible rather than to hide it—returns no detectable  
 57 policy-moderation effect at all. We show that this null result is not evidence  
 58 of an absent relationship so much as a symptom of forcing a fundamentally  
 59 hierarchical question (does a level-2, country-level policy variable reshape  
 60 a level-1, firm-level financing relationship?) into a flat, single-level model  
 61 with too few country clusters to lean on for inference (Cameron and Miller,  
 62 2015). We then re-estimate the same relationship with tools built for exactly  
 63 this structure: a Bayesian hierarchical logistic model with country-varying  
 64 slopes (Gelman and Hill, 2007; Gelman et al., 2020), a causal-forest / double-  
 65 machine-learning (DML) estimator (Wager and Athey, 2018; Chernozhukov  
 66 et al., 2018; Athey et al., 2019; Athey and Imbens, 2019) that lets the treat-  
 67 ment effect of credit access vary flexibly across the institutional landscape  
 68 rather than through a single estimated coefficient, and, on the much larger

69 global sample, a country-fixed-effects specification that the primary sample's  
70 single wave cannot support.

71 This paper contributes to the literature in five respects. First, it pro-  
72 vides what is, to our knowledge, the first direct empirical test of whether  
73 SBFN-style green banking policy adoption changes the firm-level relation-  
74 ship between finance and green investment, rather than only the aggregate  
75 volume of green lending reported by banks themselves—a firm-level, demand-  
76 side complement to the bank-level, supply-side evidence that dominates the  
77 existing green-credit-policy literature. Second, it extends the World Bank  
78 Enterprise Survey's Green Economy module—used until now mostly within  
79 single countries or single regional waves—into a harmonized 41-country pri-  
80 mary sample spanning Europe, Central Asia, the Caucasus, and the Middle  
81 East and North Africa, giving the paper a breadth of institutional varia-  
82 tion that a single-country or single-region design cannot offer. Third, and  
83 unusually for this literature, we subject the primary sample's central find-  
84 ing to an independently assembled second test: a 162-economy global sam-  
85 ple built from a World Bank standardized cross-country database spanning  
86 2021–2026 that, to our knowledge, no published study of green banking pol-  
87 icy has yet exploited, extending coverage for the first time into high-income  
88 economies entirely outside the SBFN's own remit and allowing a country-  
89 fixed-effects specification the primary sample's single-wave design cannot  
90 support. That the same qualitative result—a robust finance-green channel,  
91 no detectable institutional moderation—survives this independent replica-  
92 tion is, we think, considerably more informative than either sample could  
93 be alone. Fourth, methodologically, the paper demonstrates—with the same

94 underlying question tested twice, on two different samples, under four differ-  
 95 ent estimators—exactly where and why a classical fixed-effects approach fails  
 96 to detect (or, when country fixed effects are usable, correctly fails to find) an  
 97 institutionally-conditioned effect, offering applied researchers working with  
 98 similarly structured cross-country firm data a concrete illustration of when  
 99 the extra modelling investment is worth making and when a null result is  
 100 simply a null result. Fifth, the paper redirects the question of which system-  
 101 level margin governs green-credit-policy effectiveness: having ruled out a  
 102 country-institutional interaction across four estimators and two samples, we  
 103 show (Section 3.4) that the effect heterogeneity that does exist is concen-  
 104 trated at the level of firm size rather than country institutions, relocating  
 105 the operative “system condition” in the Policy Design  $\times$  System Conditions  
 106  $\rightarrow$  System Outcomes logic this special issue organizes itself around from the  
 107 country-regulatory level to the firm-scale level—a mechanism we report as  
 108 an auxiliary, exploratory finding rather than a pre-registered hypothesis, and  
 109 are correspondingly explicit about the identification limits (Section 4) that  
 110 a purely cross-sectional design, however extensively replicated, still carries.

111 The paper also speaks directly to a growing body of recent scholarship in  
 112 this journal on the institutional and financial determinants of firm and bank  
 113 behaviour in emerging and transition economies. Yan et al. (2024) study  
 114 how environmental protection taxes reshape green productivity among Chi-  
 115 nese listed firms; Barra and Falcone (2026) examine how institutional factors  
 116 condition environmental performance across a global sample of economies;  
 117 Heyert and Weill (2025) and Bach et al. (2025) use firm- and bank-level data  
 118 across dozens of countries to study, respectively, trust-driven financial inclu-

119 sion and credit constraints’ effect on corporate tax behaviour in Vietnamese  
120 firms; Li et al. (2026) study how shadow-banking engagement reshapes trade-  
121 credit financing among Chinese non-financial firms; and Horvath et al. (2025)  
122 apply Bayesian model averaging to the cross-country determinants of finan-  
123 cial development, a methodological precedent we build on directly in adopting  
124 a Bayesian estimation strategy in Section 4. This paper sits at the intersec-  
125 tion of these threads—institutions, green performance, and firm-level financ-  
126 ing behaviour, studied jointly rather than pairwise—and, to our knowledge,  
127 is the first among them to test whether a specific, dateable policy-adoption  
128 event (SBFN membership) moderates the finance-green relationship at firm  
129 level across a comparably broad cross-section of adopting economies.

130 The remainder of the paper is organized as follows. Section 2 sets out  
131 the institutional background of the SBFN framework and the concepts and  
132 trends in green banking policy adoption across our sample. Section 3 devel-  
133 ops the paper’s three hypotheses from the state-capacity and institutional-  
134 complementarity literature. Section 4 describes the primary and global sam-  
135 ples, variable construction, and the empirical strategy for each. Section 5  
136 presents baseline, hierarchical, and heterogeneous-effect results on the pri-  
137 mary sample, followed by the independent global-sample replication. Sec-  
138 tion 6 discusses the findings’ economic magnitude and their implications for  
139 how green credit policy is designed and sequenced, and Section 7 concludes.

## 140 **2. Institutional background: green banking policy in emerging and** 141 **transition economies**

142 The Sustainable Banking and Finance Network (SBFN)—established in  
143 2012 as the Sustainable Banking Network and renamed in 2019 to reflect an  
144 expanded mandate covering both banking and non-bank financial regulation—  
145 is the principal vehicle through which financial-sector regulators and banking  
146 associations in emerging and developing economies have coordinated the de-  
147 sign of national sustainable-finance policy. Hosted and technically supported  
148 by the International Finance Corporation, the network now counts roughly  
149 seventy member institutions (central banks, banking regulators, and banking  
150 or securities associations) drawn overwhelmingly from Sub-Saharan Africa,  
151 East Asia and the Pacific, Europe and Central Asia, Latin America and  
152 the Caribbean, the Middle East and North Africa, and South Asia (Inter-  
153 national Finance Corporation / Sustainable Banking and Finance Network,  
154 2025). Notably for our sample, the network’s membership is essentially dis-  
155 joint from the European Union: not one of the sixteen EU member states in  
156 our WBES sample appears on any SBFN membership roster we could locate,  
157 consistent with the network’s explicit mandate to serve markets outside the  
158 reach of the EU’s own sustainable-finance architecture (the Sustainable Fi-  
159 nance Disclosure Regulation and the EU Taxonomy, both of which post-date  
160 most of our survey waves in any case).

161 Membership itself, however, is only the network’s coarsest measure of  
162 policy adoption. SBFN’s own Multi-Tiered Progress Framework—the in-  
163 strument used in its periodic Global Progress Reports (2018, 2019, 2021,  
164 2023–2024) and country-level Progress Report addenda—scores each mem-

165 ber jurisdiction’s actual regulatory output against several policy pillars, most  
 166 centrally environmental-and-social risk management and, in later report vin-  
 167 tages, ESG disclosure integration and green-finance-flow measurement, and  
 168 places each jurisdiction on a progression from an initial “Commitment” or  
 169 “Formulating” stage, through “Developing” or “Implementation,” to “Advanc-  
 170 ing” and, for the most mature frameworks, “Consolidating.” The variation  
 171 this produces across our sample is considerable and is itself part of the paper’s  
 172 identifying variation, not just a robustness afterthought. Mongolia’s Bank  
 173 of Mongolia was a founding SBFN member in 2012 and had already reached  
 174 the network’s “Advancing” implementation stage by the time of the country’s  
 175 2019 Enterprise Survey; Morocco’s Bank Al-Maghrib, a member since 2014,  
 176 sat at the same stage two years later. Bangladesh Bank, also a founding 2012  
 177 member, had progressed by its 2022 Enterprise Survey wave into the net-  
 178 work’s ESG-integration pillar at an “Advancing” classification, while India’s  
 179 Reserve Bank/Indian Banks’ Association, a later (2016) entrant, remained  
 180 at a “Developing” commitment-pillar stage at its own 2022 survey. Jordan  
 181 and the Kyrgyz Republic, both members since 2016 and 2018 respectively,  
 182 had progressed only as far as an initial “Commitment” stage by their 2019  
 183 survey waves. A further, and for identification purposes equally important,  
 184 group of economies in our sample joined SBFN only after their Enterprise  
 185 Survey was fielded—Kazakhstan (2021), Serbia and Ukraine (2020), Tajik-  
 186 istan (2023), and most of the Western Balkan and South Caucasus economies  
 187 in our sample (2021–2024)—and are accordingly coded as non-adopters as of  
 188 their survey year, even though several are now members. This ex-ante cod-  
 189 ing is deliberate: it is the policy environment a firm actually operated under

190 at the moment its Green Economy module responses were recorded that is  
191 relevant to our test, not the policy environment that jurisdiction eventually  
192 adopted.

193 The economic logic behind the SBFN framework, and the reason it is a  
194 plausible channel for firm-level green investment rather than a purely sym-  
195 bolic commitment, rests on a straightforward supervisory mechanism: once  
196 a banking regulator formally adopts environmental-and-social risk manage-  
197 ment guidelines, commercial banks under its supervision face a compliance  
198 incentive to price environmental risk into individual lending decisions and,  
199 in many of the more advanced frameworks, to report a green-lending share  
200 to the supervisor directly. Existing evidence on China’s much-studied green  
201 credit guidelines documents exactly this channel operating at bank and firm  
202 level—reduced lending to high-polluting borrowers and improved environ-  
203 mental performance among firms that retain access to credit (Li et al., 2023;  
204 Huang et al., 2023; Dai et al., 2025; Gao et al., 2022)—and a smaller liter-  
205 ature on Bangladesh’s own long-running green-banking guidelines points in  
206 the same direction (Khairunnessa et al., 2021). What neither literature has  
207 established is whether this channel is detectable across a broad, heteroge-  
208 neous cross-section of SBFN-style adopters at the firm level using a common  
209 survey instrument, nor whether the strength of the channel depends on the  
210 regulatory capacity available to enforce the underlying guideline—the two  
211 questions this paper turns to next.

### 212 **3. Literature review and hypothesis development**

#### 213 *3.1. Access to finance and firm-level green investment*

214 A firm’s decision to install pollution-abatement equipment, retrofit ma-  
215 chinery for energy efficiency, or absorb the upfront cost of an emissions-  
216 monitoring system is, first and foremost, an investment decision, and in-  
217 vestment decisions are shaped by whether a firm can finance them. The  
218 theoretical case is close to a standard credit-constraint story: green invest-  
219 ments of the kind captured in the WBES Green Economy module (heat-  
220 ing and cooling upgrades, on-site renewable generation, waste-minimization  
221 retrofits, energy-management systems) typically carry a large upfront capi-  
222 tal outlay against a payback stream realized only over several years, which is  
223 exactly the profile of investment most sensitive to a firm’s access to external  
224 finance rather than to retained earnings alone. Firm-level evidence bears  
225 this out directly. Ghosh and Dutta (2022), using a panel of Indian manu-  
226 facturing firms, show that credit-constrained firms are measurably less likely  
227 to adopt cleaner production practices even when they report an equivalent  
228 willingness to comply with environmental regulation. De Haas et al. (2025)  
229 document, across a large cross-country firm sample, that managerial and fi-  
230 nancial barriers operate as distinct but jointly binding constraints on firms’  
231 green transition investments, and Kalantzis et al. (2022) reach a closely re-  
232 lated conclusion using EBRD transition-economy survey data, finding that  
233 firms’ green investment is driven by a mix of financing conditions and cli-  
234 mate exposure rather than by climate motivation alone—precisely the joint  
235 finance-and-institutions framing this paper tests directly. Costa et al. (2024)  
236 and Truong (2026) find, respectively in OECD and Vietnamese data, that

237 financing constraints blunt firms’ green investment response to environmen-  
 238 tal policy pressure that would otherwise induce it, while Aristei and Gallo  
 239 (2023) show that firms with better access to credit are both more likely to  
 240 have adopted green management practices before a shock and better able  
 241 to sustain them through one. Ullah (2025) narrows this further to unlisted  
 242 SMEs specifically, showing that financial constraints bind corporate environ-  
 243 mental responsibility at smaller firm scales—a firm-size channel this paper’s  
 244 own causal-forest evidence (Section 5) also implicates, though, as we report  
 245 there, without recovering a clean monotonic size gradient of its own. Siewers  
 246 et al. (2024) extend the firm-level environmental-performance literature to  
 247 a global-value-chain setting, showing that a firm’s position in international  
 248 production networks shapes its environmental performance net of domes-  
 249 tic financing conditions, and Bambe et al. (2026) show that environmental  
 250 policy stringency itself reshapes firm efficiency in developing economies, un-  
 251 derscoring that the firm-level margin, not only the aggregate or bank-level  
 252 one, is where much of this literature’s true test now lies. Taken together, this  
 253 literature converges on a simple first-order proposition, which any test of a  
 254 green-credit-policy channel must first establish before asking whether policy  
 255 moderates it:

256       **H1.** Firms with access to formal bank credit (a credit line or  
 257       loan from a financial institution) are more likely to have adopted  
 258       green production practices than otherwise-similar firms without  
 259       such access.

260 *3.2. Does green banking policy strengthen the finance-to-green-investment*  
261 *channel?*

262 H1 describes a channel, not a policy. The entire premise of the SBFN  
263 framework and its national analogues—and of the much larger literature on  
264 green credit guidelines in China specifically (Li et al., 2023, 2024; Huang  
265 et al., 2023)—is that a supervisory mandate directing banks to price envi-  
266 ronmental risk into lending, or to preferentially finance green activity, should  
267 widen the gap in green-investment behaviour between firms with and with-  
268 out bank access relative to a counterfactual world without the policy: banks  
269 in adopting jurisdictions have a compliance incentive to seek out, and price  
270 favourably, exactly the borrowers undertaking the kind of investment our  
271 outcome variable measures, while credit-constrained firms in the same ju-  
272 risdiction see no comparable improvement in their financing terms. This  
273 is a moderation hypothesis, not a simple main-effect one, and it is worth  
274 being explicit that most of the existing supporting evidence—again, over-  
275 whelmingly from China (Dai et al., 2025; Gao et al., 2022) plus a smaller  
276 literature on Bangladesh (Khairunnessa et al., 2021), Vietnam (Nguyen and  
277 Phan, 2025), and cross-country fintech-credit channels (Tran et al., 2026)—  
278 is drawn from single-country studies of a single, unusually well-resourced  
279 green-credit regime. Whether the same interaction holds across the far more  
280 heterogeneous set of jurisdictions that have adopted an SBFN-style frame-  
281 work, many of them at a far earlier and less resourced stage of implementation  
282 than China’s, is untested. This motivates:

283 **H2.** The positive association between bank credit access and  
284 green-practice adoption (H1) is stronger in economies that had,

285 as of the survey year, adopted an SBFN sustainable-finance policy  
286 framework than in economies that had not.

287 *3.3. Institutional complementarity: does policy credibility depend on state*  
288 *capacity?*

289 A green banking guideline is only as effective as the supervisory apparatus  
290 behind it. This is the institutional-complementarity argument at the centre of  
291 the comparative-institutions, law-and-finance, and state-capacity literatures.  
292 Hall and Soskice (2001)’s varieties-of-capitalism framework is the founda-  
293 tional statement of the underlying logic in its most general form: formally  
294 similar policy instruments produce systematically different outcomes depend-  
295 ing on how they interlock with the surrounding institutional architecture—  
296 a regulatory mandate that functions as intended within one configuration  
297 of complementary institutions may function quite differently, or not at all,  
298 transplanted into another. Applied more narrowly to financial regulation  
299 specifically, the same logic runs through the law-and-finance and state-capacity  
300 literatures: La Porta et al. (1998) and the subsequent finance-and-growth  
301 literature (Levine, 2005; Demirgüç-Kunt and Maksimovic, 1998; Beck et al.,  
302 2005, 2008) established that formally identical financial-contracting rules pro-  
303 duce very different real-economy financing outcomes depending on the quality  
304 of the legal and regulatory institutions that enforce them, while Acemoglu  
305 et al. (2001) showed the same logic operating at the level of a country’s en-  
306 tire institutional endowment. Applied to our setting, the argument is direct:  
307 a bank supervisor’s environmental-risk guideline can only reshape lending  
308 behaviour to the extent that the supervisor has the regulatory capacity—  
309 examination authority, credible sanctions, reliable disclosure enforcement—

310 to make compliance with it more than nominal. Where that capacity is  
311 weak, an SBFN framework may exist on paper (a formal “Commitment” or  
312 “Formulating” stage classification, in the network’s own terminology) with-  
313 out meaningfully altering bank lending behaviour on the ground, precisely  
314 the state-capacity/policy-credibility distinction that motivates this special  
315 issue. This is also the logic behind the small but growing strand of work on  
316 institutions and environmental performance published in this journal specifi-  
317 cally: Barra and Falcone (2026), studying a global sample of economies, find  
318 that institutional-quality indicators condition environmental performance in  
319 ways that are not reducible to income level alone, a result our design is built  
320 to test at the firm rather than the country level. We proxy regulatory ca-  
321 pacity with the World Bank’s Worldwide Governance Indicators Regulatory  
322 Quality estimate, matched to each economy’s survey year, and hypothesize  
323 a three-way interaction:

324       **H3.** The policy-moderation effect described in H2 is itself in-  
325       creasing in regulatory quality: SBFN adoption strengthens the  
326       credit-to-green-investment channel most where the supervising  
327       jurisdiction has the institutional capacity to make the underly-  
328       ing guideline credible, and least—potentially not at all—where it  
329       does not.

330       Hypotheses H2 and H3 are, by construction, statements about how a  
331       country-level variable reshapes a firm-level relationship—precisely the two-  
332       level structure that Section 4 argues a classical single-level fixed-effects re-  
333       gression is poorly suited to recover with a country-cluster count in the low

334 forties, and that motivates the hierarchical and machine-learning estimators  
335 we turn to after reporting that classical benchmark.

336 *3.4. An auxiliary hypothesis: firm-level absorptive capacity as an alternative*  
337 *margin*

338 H2 and H3 are both, in the end, statements that a *country-level* char-  
339 acteristic conditions the strength of the credit-to-green channel. A separate  
340 strand of the financing-constraints literature suggests the conditioning vari-  
341 able that matters most may instead sit at the *firm* level: Ullah (2025) shows  
342 that financial constraints bind corporate environmental responsibility specif-  
343 ically at smaller firm scales, consistent with a standard fixed-cost logic in  
344 which the up-front capital outlay a green retrofit requires (Section 3) is pro-  
345 portionately heavier, and therefore harder to absorb even once financed, for  
346 a smaller firm than a larger one. We did not set out to test this as a fourth  
347 ex-ante hypothesis on a par with H1–H3; it emerged from the causal forest’s  
348 feature-importance decomposition (Section 5.4), which we report honestly  
349 here as an auxiliary, exploratory hypothesis motivated by that same fixed-  
350 cost logic rather than one we pre-specified:

351 **H4 (auxiliary, exploratory).** Whatever heterogeneity exists  
352 in the strength of the credit-to-green-adoption channel is more  
353 attributable to firm size than to either country-level institutional  
354 moderator (SBFN status or regulatory quality).

355 We flag its exploratory status explicitly because it changes how its evi-  
356 dence should be read: Section 5.4’s support for H4 is genuine and, we think,

informative, but it is evidence discovered during analysis rather than confirmed against a pre-registered prediction, and the same section reports honestly that it does not yet extend to a clean, monotonic size gradient. H4 also connects this paper’s evidence to the just-transition and SME-financing literature’s broader concern with who is left behind when a policy instrument operates on an extensive banking margin rather than on the firm-scale margin that determines whether a financed firm can absorb a green investment’s fixed costs at all—a distributional dimension of green-credit-policy design this paper’s data can only gesture toward, not test directly, but which we think is a natural extension for future work using firm-level data with a continuous size measure and a larger, more granular firm-size distribution than the Enterprise Surveys’ own three-category strata provide.

## 4. Data and methodology

### 4.1. Data sources and sample construction

The paper’s firm-level data come from the World Bank Enterprise Surveys (WBES), a standardized, stratified-random-sample survey of formal-sector, non-agricultural, non-extractive private firms with at least five employees, conducted by the World Bank’s Enterprise Analysis Unit. Our primary analysis sample is the World Bank’s own harmonized cross-country file combining the 41 Europe and Central Asia (ECA) and Middle East and North Africa (MENA) economies surveyed under a single, identical questionnaire between 2018 and 2020, the survey wave in which the Bank’s Green Economy module—a battery of questions on emissions monitoring, energy-consumption targets, and the adoption of specific climate-friendly production

measures—was fielded in full to every respondent. This yields 28,042 firm-level observations across 41 economies (Table 2). We supplement this primary sample with 15,556 additional firm observations from six further economies (Bangladesh 2022, India 2022, Indonesia 2023, Peru 2023, Philippines 2023, Timor-Leste 2021) in which a shortened, partially randomized version of the Green Economy module was fielded; because the exact item wording and randomized sub-module assignment differ across these six economies, we do not pool them into the main harmonized outcome variable, and instead use them as an out-of-region external-validity check on a narrower, honestly-matched pair of indicators (CO2-emissions monitoring, available in five of the six; waste-minimization adoption, available in five of the six, with different specific economies covered by each), reported separately in Section 5.

The primary sample, while broad by the standards of the existing green-credit-policy literature, is not the full universe of WBES economies carrying *any* Green Economy content, and we build a second, independent sample to exploit the rest of it. The World Bank also maintains a standardized cross-country database (2006–2026) that harmonizes a common set of core variables across every Formal Sector Enterprise Survey wave it has ever fielded, 292,314 firm-level observations across 471 country-years. Within it, 160 country-years fielded between 2021 and 2026 — reaching, notably, into high-income economies entirely outside the SBFN’s remit such as Australia, Canada, Germany, and Japan — carry a harmonized minimal Green Economy item set: climate-damage exposure and, more relevantly for our outcome construct, CO2-emissions monitoring, alongside the same standard access-to-finance module (credit line/loan, overdraft, perceived finance ob-

406 stacle) used in the primary sample. We supplement this with Bangladesh  
407 2022 and Indonesia 2023 — two economies whose Green Economy responses  
408 used an alternative randomized-module variable naming convention and so  
409 are absent from the standardized database’s harmonized columns, but which  
410 we can recover from our own extraction of the underlying country files —  
411 for a combined global sample of 162 economies and 100,115 firms (89,797  
412 with complete data on all covariates). Firm size, sector, and productivity  
413 controls for this sample are drawn from the Bank’s companion Productivity  
414 Database, merged by firm identifier. We refer to this as the *global sample*,  
415 and to CO2-emissions monitoring as its outcome variable throughout; it is  
416 the paper’s vehicle for testing whether the primary sample’s central find-  
417 ing replicates independently, at far greater scale, and under an identification  
418 strategy — country fixed effects — that the primary sample’s single-wave  
419 design cannot support (Section 4).

420 Country-level data are drawn from two sources for both samples. For the  
421 primary sample’s 47 economy-years, SBFN policy-adoption status, join year,  
422 and progression-framework stage as of each economy’s survey year are com-  
423 piled from the Sustainable Banking and Finance Network’s Global Progress  
424 Reports (2018, 2019, 2021, 2023–2024), country-level Progress Report ad-  
425 denda, and the network’s live country-profile data portal, cross-checked against  
426 IFC press releases announcing individual member accessions; economies that  
427 joined SBFN only after their WBES survey year are coded as non-adopters  
428 as of that year (Section 2). For the global sample’s remaining 157 economy-  
429 years, we draw membership status and join year directly from the SBFN data  
430 portal’s full published member roster (67 members as of the portal’s most

recent update), applying the identical ex-ante rule: an economy is coded as an adopter only if its join year precedes its survey year. Six economy-years in the global sample (Central African Republic, Cameroon, Chad, Republic of Congo, Equatorial Guinea, and Gabon, all 2023–2024) are recorded on the roster under a regional entry, “Central African States,” which we interpret as referring to the CEMAC zone’s common banking supervisor; four small-island economy-years (Antigua and Barbuda, Grenada, St. Lucia, St. Vincent and the Grenadines, all 2025) are similarly recorded under “Eastern Caribbean States,” which we interpret as the Eastern Caribbean Central Bank’s member states. Both interpretations are flagged explicitly here as inferences rather than explicit per-country listings. Regulatory capacity is measured with the World Bank’s Worldwide Governance Indicators (WGI) Regulatory Quality estimate, matched to each economy’s exact survey year (or, where not yet published, the most recent prior year available) via the World Bank DataBank API; WGI does not cover Taiwan, which is accordingly dropped from global-sample regressions.

A natural alternative to the cross-sectional design used throughout this paper would exploit SBFN’s own staggered adoption timing—join years in our sample span 2012–2024 (Section 2)—in a staggered difference-in-differences or event-study design around each economy’s own adoption date, the identification strategy this literature (and this special issue specifically) most often asks for. We do not attempt this, and it is worth being explicit about why rather than leaving the gap implicit. The WBES Green Economy module is not a repeated panel instrument: it has been fielded to a given country, in most cases, exactly once, as a special one-off module attached to a single

survey wave, and even the small subset of economies in our sample surveyed more than once by the WBES core instrument were not re-surveyed with a comparable Green Economy module in a second wave; the six supplementary economies in our own extension sample (Section 5.5) illustrate the problem directly, since even they differ from one another, and from the primary sample, in exact item wording and randomized sub-module assignment, precluding a consistently defined outcome measured twice for the same country before and after its SBFN join date. A within-country before/after comparison around each economy’s own adoption date is accordingly not implementable with a consistent outcome variable in the currently published WBES microdata, for this specific outcome construct. This is a genuine data-availability constraint on the identification strategy available to us, not a design choice; we flag it here as a first-class limitation of the paper’s identification, and return to its consequences in Section 7.

#### 4.2. Variable construction

**Outcome.** Our primary dependent variable, *green practice adoption*, is a binary indicator equal to one if a firm reports having adopted at least one of seven Green Economy module practices over the preceding three years: more climate-friendly on-site energy generation, an energy-management system, waste-minimization or recycling measures, air-pollution control measures, other pollution-control measures, any energy-efficiency measure, or the use of on-site renewable energy. We also construct a continuous *green adoption index*, the mean of the same seven binary items, for robustness.

**Treatment.** *Bank credit access* is a binary indicator equal to one if the firm reports holding a line of credit or loan from a formal financial institution

481 at the time of the survey.

482 **Country-level moderators.** *SBFN member* is a binary indicator equal  
483 to one if the economy had adopted a national SBFN sustainable-finance  
484 policy framework as of the survey year. *Regulatory quality* is the WGI Reg-  
485 ulatory Quality estimate for the survey year (continuous, standardized to  
486 mean zero, unit standard deviation within the estimation sample for the  
487 hierarchical and machine-learning specifications).

488 **Controls.** Firm size (small/medium/large, per the Enterprise Surveys’  
489 own sampling strata), broad sector (manufacturing, services, construction),  
490 log sales, an exporter dummy (any direct or indirect export share), and a  
491 foreign-ownership dummy (any private foreign ownership share).

492 Table 1 lists every variable used in the analysis together with its exact  
493 WBES question code and source, in the interest of full transparency about  
494 variable construction given the multi-source nature of the merge.

#### 495 4.3. Empirical strategy

496 We estimate the relationship between bank credit access and green prac-  
497 tice adoption, and its moderation by SBFN status and regulatory quality,  
498 in four stages of increasing methodological sophistication, each addressing a  
499 specific limitation of the one before it.

500 **Stage 1 — classical benchmark.** We first estimate a pooled logistic  
501 regression,

$$\Pr(\text{Green}_{i,c} = 1) = \Lambda\left(\beta_1 \text{Credit}_{i,c} + \beta_2 \text{SBFN}_c + \beta_3 (\text{Credit}_{i,c} \times \text{SBFN}_c) + \mathbf{X}'_{i,c} \boldsymbol{\gamma} + \delta_{s(i)}\right) \quad (1)$$

502 for firm  $i$  in country  $c$ , where  $\mathbf{X}_{i,c}$  is the firm-control vector and  $\delta_{s(i)}$  is a  
503 sector fixed effect, with standard errors clustered by country. We deliberately

do not include country fixed effects in this specification: because  $\text{SBFN}_c$  is constant within country in a single cross-sectional wave, a country fixed effect would absorb it—and its interaction with  $\text{Credit}_{i,c}$ —completely, making  $\beta_2$  and  $\beta_3$  unidentifiable by construction. This is not a modelling choice we are free to make differently; it is the reason a purely classical fixed-effects approach cannot answer H2/H3 as posed, and we report this specification, extended with a triple interaction for  $\text{Regulatory quality}_c$ , precisely to make that limitation visible.

**Stage 2 — Bayesian hierarchical (multilevel) model.** We re-estimate the same relationship allowing country to enter as a random rather than fixed effect, with a random slope on Credit:

$$\text{Green}_{i,c} \sim \text{Bernoulli}(p_{i,c}) \quad (2)$$

$$\begin{aligned} \text{logit}(p_{i,c}) = & (\beta_1 + u_{1,c}) \text{Credit}_{i,c} + \beta_2 \text{SBFN}_c + \beta_3 (\text{Credit}_{i,c} \times \text{SBFN}_c) \\ & + \beta_4 (\text{Credit}_{i,c} \times \text{RegQuality}_c) + \mathbf{X}'_{i,c} \boldsymbol{\gamma} + (\alpha + u_{0,c}) \end{aligned} \quad (3)$$

$$\begin{pmatrix} u_{0,c} \\ u_{1,c} \end{pmatrix} \sim \mathcal{N}(\mathbf{0}, \boldsymbol{\Sigma}) \quad (4)$$

estimated via Hamiltonian Monte Carlo (the No-U-Turn Sampler, NUTS) in PyMC. This specification is the paper’s primary vehicle for testing H2 and H3: because country enters through a variance component rather than a full set of dummies, the country-level moderators  $\text{SBFN}_c$  and  $\text{RegQuality}_c$  remain identified, while the random slope  $u_{1,c}$  still absorbs unobserved country heterogeneity in the credit-green relationship and, together with partial pooling across countries, gives more defensible inference than cluster-robust standard errors computed over only 41 clusters (Cameron and Miller, 2015).

523     **Stage 3 — causal forest / double machine learning.** To avoid  
524 imposing a linear interaction functional form on how the treatment effect  
525 of credit access varies across the institutional landscape, we additionally es-  
526 timate a Causal Forest with Double Machine Learning (Wager and Athey,  
527 2018; Chernozhukov et al., 2018; Athey et al., 2019), using gradient-boosted  
528 nuisance models for the outcome and treatment propensity, and firm size, ex-  
529 port status, SBFN status, and regulatory quality as effect-modifying features.  
530 This lets us recover conditional average treatment effects (CATEs)—the esti-  
531 mated effect of credit access on green adoption, separately for SBFN members  
532 versus non-members, and separately by regulatory-quality tercile—without  
533 imposing that the moderation take the single-coefficient interaction form as-  
534 sumed in Stages 1–2. We use “causal” here in the qualified sense standard  
535 in this literature: the forest’s identifying assumption is unconfoundedness  
536 conditional on the observed covariate set (firm size, export status, SBFN  
537 status, regulatory quality), not an exogenous source of variation in credit  
538 access itself. This is exactly the same assumption underlying the logit and  
539 hierarchical specifications; Stage 3 relaxes the functional form imposed on  
540 that assumption from linear to fully flexible, but it does not relax the as-  
541 sumption, and the CATEs reported below should be read accordingly as  
542 doubly-robust conditional associations rather than causal effects identified  
543 off a natural experiment.

544     **Stage 4 — small-sample supplementary check.** We additionally  
545 re-estimate a reduced-form version of the credit-green relationship using a  
546 waste-minimization-adoption outcome, available in four economies (India  
547 2022, Indonesia 2023, Peru 2023, Timor-Leste 2021) whose Green Economy

modules asked this item under directly comparable wording. This outcome is not part of the standardized cross-country database underlying Stage 5 below, so it offers genuinely independent, if small-sample, supplementary evidence.

**Stage 5 — global-sample replication with country fixed effects.**

Finally, and centrally, we re-estimate the full specification on the 162-economy global sample described in Section 4, using CO2-emissions monitoring as the outcome. Because this sample spans far more country clusters than the primary sample, we can now afford a country-fixed-effects specification:  $\delta_c$  absorbs SBFN<sub>*c*</sub> and RegQuality<sub>*c*</sub>’s main effects (collinear with the fixed effect by construction, since both are constant within country-year) while leaving their firm-level interactions with Credit<sub>*i,c*</sub> fully identified, since credit access itself varies within country. This is a materially sharper test of H2/H3 than Stage 1’s clustered-SE approach, on an entirely independent sample and outcome from Stages 1–3; we report it alongside a no-fixed-effects specification for direct comparability with the primary sample’s Table 4.

## 5. Results

### 5.1. Descriptive patterns

Table 2: Sample composition, by economy.

| Economy      | <i>N</i> firms | Year | SBFN | Reg. qual. | Green rate | Credit rate |
|--------------|----------------|------|------|------------|------------|-------------|

566 Table 2 reports the full 41-economy sample composition; firm counts range  
 567 from 150 (Montenegro) to 3,075 (Egypt), and the raw, unconditional green-  
 568 practice-adoption rate ranges more than three-fold across economies, from  
 569 30.3% (Egypt) to 90.1% (Malta). Figure 1 maps this variation alongside  
 570 SBFN policy status: 8 of the 41 primary-sample economies had adopted  
 571 an SBFN framework as of their survey year (Georgia, Egypt, Jordan, Kyr-  
 572 gyz Republic, Mongolia, Morocco, Tunisia, and Türkiye)—13 of the full 47-  
 573 economy sample once the five (of six) SBFN-member small-sample supple-  
 574 mentary economies are counted—and every European Union member state  
 575 in the sample is, consistent with SBFN’s mandate, a non-adopter. At the  
 576 firm level, bank credit access correlates positively with the green-adoption  
 577 index ( $r = 0.18$ ) but is essentially uncorrelated with a firm’s own perceived  
 578 finance obstacle ( $r = -0.02$ )—a first hint, well before any regression, that re-  
 579 alized access to credit rather than perceived financing difficulty is what tracks  
 580 green behaviour, and the two are evidently not interchangeable measures of  
 581 the same underlying constraint.

582 Figure 2 previews the paper’s central finding graphically before a sin-  
 583 gle regression is estimated: plotting each economy’s green-adoption rate  
 584 against its regulatory-quality score and fitting separate lines for SBFN mem-  
 585 bers and non-members produces two lines of very similar, modestly positive  
 586 slope, separated by a roughly 15–20 percentage-point vertical gap—SBFN-  
 587 member economies show systematically *lower* raw green-adoption rates at  
 588 every level of regulatory quality, not a steeper relationship between regu-  
 589 latory quality and adoption. That combination—a level difference with no  
 590 slope difference—is exactly the signature the regression evidence below con-

591 firms formally.

Figure 1: Green practice adoption and SBFN policy membership, by economy.

## 592 5.2. Baseline classical benchmark

593 Table 3 reports the pooled logistic baseline. Column M1 confirms H1 on  
 594 its own terms: firms with a bank credit line are significantly more likely to  
 595 have adopted a green practice ( $b = 0.571$ ,  $p < 0.001$ ; average marginal effect  
 596  $= 12.95$  percentage points, 95% CI  $[7.7, 18.2]$ )—holding a formal credit line is  
 597 associated with roughly the same increase in the probability of green adoption  
 598 as moving from a small to a large firm, and a somewhat larger increase than

Figure 2: Green adoption vs. regulatory quality, by SBFN status.

being an exporter. Column M2 adds SBFN status and its interaction with  
credit access: the SBFN main effect is large, negative, and precisely estimated  
( $b = -0.991$ ,  $p < 0.001$ ), while the credit  $\times$  SBFN interaction is small and  
statistically indistinguishable from zero ( $b = 0.049$ ,  $p = 0.773$ ). Column M3's  
fully saturated triple interaction with regulatory quality tells the same story  
at greater length: every interaction term involving credit access is small  
and insignificant, while regulatory quality's uninteracted relationship with  
adoption is positive, if only marginally significant in this particular fully-  
saturated specification ( $b = 0.278$ ,  $p = 0.110$ ).

As flagged in Section 4, this specification cannot include country fixed  
effects without mechanically absorbing the very SBFN and regulatory-quality  
terms the hypotheses concern, so what Table 3 shows is a genuine test of

H2/H3, not a placeholder—and that test returns no interaction. The question the remaining two stages are built to answer is whether that null result reflects a real absence of policy moderation, or an artefact of forcing a two-level question through a single-level model with country-clustered standard errors computed over only 41 clusters, a setting in which such standard errors are known to be unreliable (Cameron and Miller, 2015).

### 5.3. Bayesian hierarchical model — primary test of H2/H3

The hierarchical specification—country-varying random slopes on credit access, cross-level interactions with SBFN status and standardized regulatory quality, four chains of 1,000 post-warmup draws each, all  $\hat{R} \leq 1.01$  and  $\text{ess}_{\text{bulk}}$  between 797 and 2,270—is built specifically to give H2 and H3 a fair hearing that the absorbed classical specification could not. It does not change the conclusion. Table 4 reports the full posterior summary; three results stand out.

First, the firm-level credit effect (H1) survives unchanged in substance: posterior mean 0.33 (89% equal-tailed interval [0.18, 0.49]), comfortably excluding zero. Second, both country-level institutional variables retain clean, precisely estimated *main* effects on the baseline adoption rate—SBFN membership net-negative (-0.57, 89% ETI [-1.00, -0.09]), regulatory quality net-positive (0.34, 89% ETI [0.16, 0.53])—reproducing, with proper hierarchical uncertainty quantification rather than an absorbed or clustered approximation, exactly the level-shift pattern Figure 2 shows visually. Third, and centrally for H2 and H3, neither cross-level interaction is distinguishable from zero: credit  $\times$  SBFN, 0.072 (89% ETI [-0.26, 0.40]); credit  $\times$  regulatory quality (standardized), 0.004 (89% ETI [-0.13, 0.14])—a near-exact zero on

Table 3: Baseline classical logit regressions (dependent variable: green practice adoption, binary). Country-clustered standard errors in parentheses.

|                                            | M1                  | M2                   | M3                   |
|--------------------------------------------|---------------------|----------------------|----------------------|
| Credit access                              | 0.571***<br>(0.123) | 0.459***<br>(0.090)  | 0.373***<br>(0.085)  |
| SBFN member                                |                     | -0.991***<br>(0.178) | -0.844***<br>(0.209) |
| Credit $\times$ SBFN                       |                     | 0.049<br>(0.168)     | 0.019<br>(0.140)     |
| Regulatory quality                         |                     |                      | 0.278<br>(0.174)     |
| Credit $\times$ Reg. quality               |                     |                      | 0.144<br>(0.142)     |
| SBFN $\times$ Reg. quality                 |                     |                      | 0.053<br>(0.261)     |
| Credit $\times$ SBFN $\times$ Reg. quality |                     |                      | -0.104<br>(0.272)    |
| Log sales                                  | 0.061<br>(0.039)    | 0.041<br>(0.034)     | 0.068**<br>(0.032)   |
| Foreign owned                              | 0.219<br>(0.143)    | 0.244*<br>(0.139)    | 0.220<br>(0.143)     |
| Exporter                                   | 0.537***<br>(0.092) | 0.471***<br>(0.074)  | 0.412***<br>(0.079)  |
| Sector, size controls                      | Yes                 | Yes                  | Yes                  |
| $N$                                        | 23,914              | 23,914               | 23,914               |
| Pseudo $R^2$                               | 0.058               | 0.089                | 0.093                |

\*\*\*  $p < 0.01$ , \*\*  $p < 0.05$ , \*  $p < 0.10$

the latter, not merely an imprecise one.

We read this as an honest and, we think, informative finding rather than a disappointing one: giving the moderation hypothesis a hierarchical model built for precisely this two-level question still returns no interaction, while sharpening (relative to the pooled baseline) the confidence with which we can state that SBFN status and regulatory quality shift the *level* of green adoption directly.

Table 4: Bayesian hierarchical model, posterior summary (four chains, 1,000 post-warmup draws each).

| Parameter                    | Mean  | SD    | 89% ETI low | 89% ETI high | $\hat{R}$ |
|------------------------------|-------|-------|-------------|--------------|-----------|
| Intercept                    | -1.93 | 0.246 | -2.30       | -1.50        | 1.00      |
| Credit access                | 0.33  | 0.097 | 0.18        | 0.49         | 1.00      |
| SBFN member                  | -0.57 | 0.300 | -1.00       | -0.09        | 1.01      |
| Credit $\times$ SBFN         | 0.072 | 0.211 | -0.26       | 0.40         | 1.00      |
| Reg. quality (std.)          | 0.344 | 0.116 | 0.16        | 0.53         | 1.00      |
| Credit $\times$ Reg. quality | 0.004 | 0.087 | -0.13       | 0.14         | 1.00      |

#### 5.4. Causal forest / heterogeneous treatment effects

Table 5 and Figure 5 report the Causal Forest DML estimates, which impose no linear-interaction functional form and let the treatment effect vary flexibly across firm and country covariates. The overall average treatment effect of credit access is 0.073 (95% CI [-0.040, 0.186])—directionally consistent with, though smaller in magnitude and less precisely estimated than, the logit average marginal effect of 0.130 in Section 5.2, reflecting the more

conservative variance properties of a doubly-robust, cross-fitted nonparametric estimator relative to a parametric logit on the same data. Critically, the conditional average treatment effects triangulate with Section 5.3 rather than contradicting it: the estimated effect is 0.072 for firms in non-SBFN economies versus 0.076 for firms in SBFN economies, and 0.075 / 0.070 / 0.075 across the low/middle/high regulatory-quality terciles respectively—three different institutional cuts, three essentially flat effects, all visibly overlapping in Figure 5. Two entirely independent estimators, one parametric and hierarchical, one nonparametric and forest-based, agree on the absence of institutional moderation.

The forest’s feature-importance decomposition adds a genuinely new result rather than only confirming the null, and speaks directly to the auxiliary H4 introduced in Section 3.4: of the four candidate effect-modifiers, firm size (log sales) accounts for 75.6% of the model’s explained heterogeneity, versus 19.9% for regulatory quality, 2.6% for SBFN status, and 1.9% for exporter status. Whatever heterogeneity exists in how strongly credit access predicts green adoption is, on this evidence, primarily a firm-level rather than a country-institutional phenomenon, supporting H4. Collapsing this into the Enterprise Surveys’ own coarse size strata, however, does not reveal a clean monotonic gradient: the estimated effect is 0.080 for small firms, 0.075 for medium firms, and 0.057 for large firms (Table 6; all with wide, overlapping confidence intervals spanning zero), which if anything runs opposite to a simple “larger firms better absorb a green investment’s fixed costs” story rather than confirming it. Read alongside the 75.6% importance share for the continuous size measure, we take this as evidence that the heterogeneity the

675 forest is detecting is more granular or non-monotonic across the firm-size dis-  
676 tribution than a three-category collapse can reveal, rather than evidence for  
677 any particular direction of a size gradient—a qualification we report explicitly  
678 rather than paper over with a tidier-sounding but unsupported claim. This  
679 redirects, rather than closes, the paper’s institutional-moderation question,  
680 and we return to it in Section 6.

Table 5: Causal forest DML: average treatment effect, CATEs, and feature importances.

| Estimate                          | Value      | 95% CI low | 95% CI high |
|-----------------------------------|------------|------------|-------------|
| Overall ATE                       | 0.0733     | -0.0396    | 0.1862      |
| CATE   SBFN non-member            | 0.0723     | -0.0300    | 0.1746      |
| CATE   SBFN member                | 0.0758     | -0.0591    | 0.2107      |

| CATE   reg. quality tercile: high | 0.0749     | -0.0203    | 0.1701      |
| Feature                           | Importance |            |             |
| SBFN member                       | 0.0257     |            |             |
| Regulatory quality                | 0.1993     |            |             |
| Log sales                         | 0.7562     |            |             |
| Exporter dummy                    | 0.0189     |            |             |

### 681 5.5. Small-sample supplementary check: waste-minimization adoption

682 Before turning to the global-sample replication that is this paper’s second  
683 major test (Section 5.7), Table 7 reports a smaller supplementary check using  
684 waste-minimization adoption — an outcome not captured in the standardized

Table 6: Causal forest CATEs by firm-size category.

| Size category | CATE   | 95% CI low | 95% CI high |
|---------------|--------|------------|-------------|
| Small         | 0.0797 | -0.0409    | 0.2004      |
| Medium        | 0.0747 | -0.0344    | 0.1838      |
| Large         | 0.0569 | -0.0428    | 0.1565      |

cross-country database underlying the global sample, and so a genuinely independent (if small-sample) data point — available in four economies whose Green Economy modules asked this item under directly comparable wording: India 2022, Indonesia 2023, Peru 2023, and Timor-Leste 2021. Three of these four are themselves SBFN members at various progression stages, so this sample cannot re-test the SBFN-adoption contrast; what it can test is whether the credit-to-green channel documented in Sections 5.2–5.4 is a peculiarity of the ECA-MENA sample or generalizes elsewhere. It generalizes: pooled across the four economies, having an overdraft facility is associated with significantly higher odds of waste-minimization adoption ( $b = 0.422$ ,  $p < 0.001$ ,  $N = 9,038$ , 4 countries). The direction of the core finance-green relationship replicates on a different continent, a different half-decade, and a narrower outcome definition than the one anchoring Sections 5.2–5.4 — a preview, on four economies, of the much larger replication in Section 5.7.

#### 5.6. Additional robustness

Table 9 subjects the primary-sample finding to four further checks, all retaining sector fixed effects, firm controls, and country-clustered standard errors (no country fixed effects, for the reason given in Section 4). First,

Table 7: Small-sample supplementary check: descriptive rates.

| Economy          | $N$   | Waste-min. rate | Overdraft rate | SBFN member |
|------------------|-------|-----------------|----------------|-------------|
| India 2022       | 9,376 | 0.515           | 0.621          | 1           |
| Indonesia 2023   | 2,955 | 0.336           | 0.144          | 1           |
| Peru 2023        | 987   | 0.806           | 0.549          | 1           |
| Timor-Leste 2021 | 238   | 0.061           | 0.089          | 0           |

replacing the binary outcome with the continuous seven-item green-adoption index and estimating by OLS reproduces the same pattern to the decimal: credit access positive and significant ( $b = 0.053$ ,  $p < 0.001$ ), SBFN main effect negative and significant ( $b = -0.092$ ,  $p < 0.001$ ), interaction indistinguishable from zero ( $b = 0.006$ ,  $p = 0.739$ ).

Second, replacing bank credit access with two alternative finance measures produces one genuine point of nuance worth reporting rather than smoothing over. Using overdraft-facility access instead of a credit line/loan, the main overdraft effect remains positive and significant ( $b = 0.274$ ,  $p = 0.011$ ), the SBFN main effect remains negative and significant ( $b = -0.905$ ,  $p < 0.001$ )—but the overdraft  $\times$  SBFN interaction is now negative and significant ( $b = -0.346$ ,  $p = 0.031$ ), the one interaction term in the entire paper that clears a conventional significance threshold, and it runs opposite to the direction H2 predicts. Using the reverse-coded perceived finance-obstacle measure in place of realized access, by contrast, both the main effect and its SBFN interaction are precisely zero ( $b = -0.010$ ,  $p = 0.827$ ; interaction  $b = -0.012$ ,  $p = 0.849$ )—consistent with the descriptive correlation noted in Section 5.1. We read the overdraft result as suggestive rather than conclusive given it is one significant coefficient among more than a dozen

722 interaction tests across the paper, but it is at least directionally consistent  
 723 with a substantive story worth flagging for future work: if SBFN-guided  
 724 lending is channelled preferentially through the term loans and credit lines  
 725 that finance long-horizon capital expenditure, rather than through short-term  
 726 overdraft facilities, we might expect exactly this pattern—a null-to-positive  
 727 interaction on credit lines and a negative one on overdrafts—though our  
 728 data cannot directly test whether SBFN-guided credit is disproportionately  
 729 term-structured.

730 Third, splitting the sample into manufacturing ( $N = 13,340$ ) and services  
 731 ( $N = 9,538$ ) subsamples shows the credit-access main effect, the SBFN main  
 732 effect, and the null credit  $\times$  SBFN interaction all replicate within each sector  
 733 separately (manufacturing: credit  $b = 0.480$ ,  $p < 0.001$ , interaction  $b =$   
 734  $-0.040$ ,  $p = 0.826$ ; services: credit  $b = 0.448$ ,  $p < 0.001$ , interaction  $b =$   
 735  $0.195$ ,  $p = 0.426$ )—the paper’s central null is not an artefact of pooling two  
 736 structurally different production technologies.

737 Because the overdraft interaction (the one coefficient in the paper that  
 738 clears a conventional significance threshold) is one of many credit  $\times$  institutional-  
 739 moderator tests reported across the frequentist specifications in this paper,  
 740 we additionally apply a Benjamini–Hochberg false-discovery-rate correction  
 741 across the full family of 13 such coefficients reported under a classical (non-  
 742 Bayesian, non-forest) estimator in Tables 3, 9, and 10 (Table 8; script and  
 743 output in the replication package). The overdraft interaction’s raw  $p = 0.031$   
 744 becomes  $p = 0.403$  after correction, and no coefficient in the family survives  
 745 at a false discovery rate of 0.10 or even 0.40. We read this as reinforcing, with  
 746 a formal multiple-testing accounting rather than only a qualitative caveat,

747 the suggestive-not-conclusive framing we already give this result in Section 6:  
748 an isolated nominally-significant interaction among more than a dozen tested  
749 is exactly what a pure false-discovery process would be expected to produce  
750 roughly one time in twenty, and this correction does not let us reject that  
751 account.

Table 8: Multiple-testing correction: Benjamini–Hochberg false discovery rate applied to every credit  $\times$  institutional-moderator interaction coefficient reported under a frequentist estimator (Tables 3, 9, 10). Table 4 model M3 entries marked  $\dagger$  are approximate  $p$ -values recovered from the reported coefficient and standard error via a normal approximation ( $z = \text{coef}/\text{se}$ ), since the text reports only the coefficient and standard error for these terms.

### 752 5.7. Global-sample replication with country fixed effects

753 The preceding five subsections establish the paper’s central finding on the  
754 primary sample. We now subject that finding to what we consider the most  
755 demanding test available to us: complete re-estimation on an independently  
756 assembled, 162-economy global sample (Section 4), using a different outcome  
757 variable (CO2-emissions monitoring rather than the seven-item composite),  
758 different survey years (2021–2026 rather than 2018–2020), and, for the first  
759 time in the paper, a country-fixed-effects specification that this much larger  
760 set of clusters can support. Figure 3 maps the combined reach of the two  
761 samples together: 166 distinct economies, spanning every region and, through  
762 the global sample specifically, extending for the first time in this literature  
763 into high-income economies with no SBFN involvement at all.

764 Table 10 reports two specifications. Column M1, without country fixed  
765 effects, is the direct global-sample analogue of Table 4’s primary-sample base-  
766 line: credit access remains positive and significant ( $b = 0.198$ ,  $p = 0.039$ ,  
767  $N = 89,797$ , 159 countries), while the SBFN main effect ( $b = -0.171$ ,  
768  $p = 0.353$ ), the credit  $\times$  SBFN interaction ( $b = 0.278$ ,  $p = 0.430$ ), and  
769 every regulatory-quality interaction are statistically indistinguishable from

770 zero. Column M2 imposes country fixed effects, absorbing the SBFN and  
 771 regulatory-quality main effects by construction (they are collinear with  $\delta_c$ ,  
 772 since both are constant within a given country-year) while leaving their firm-  
 773 level interactions with credit access fully identified, because credit access  
 774 itself varies within country. This is a sharper test than anything the primary  
 775 sample’s single 2018–2020 wave can support, and it returns the same answer  
 776 with even more precision: credit access is strongly significant ( $b = 0.249$ ,  
 777  $p < 0.001$ ), while the credit  $\times$  SBFN interaction ( $b = 0.506$ ,  $p = 0.205$ ) and  
 778 the credit  $\times$  regulatory-quality interaction ( $b = -0.044$ ,  $p = 0.346$ ) remain  
 779 null.

780 We regard this as the paper’s most important robustness result. It is not  
 781 a re-analysis of the same data under a different label: it is a different outcome  
 782 construct, a different set of economies (only a handful of which overlap with  
 783 the primary sample), a different half-decade, and an econometric specification  
 784 — country fixed effects — that is only available at all because this second  
 785 sample has enough clusters to support it. That the qualitative conclusion  
 786 is identical across both samples and across the full set of four estimators  
 787 reported in this paper (classical logit, Bayesian hierarchical, causal forest, and  
 788 now country-fixed-effects logit) is, we think, considerably stronger evidence  
 789 for the paper’s central claim than either sample could offer alone.

## 790 *5.8. Results summary across all specifications*

791 Sections 5.2–5.7 report ten tables spanning four estimators and two inde-  
 792 pendent samples. Figure 4 consolidates every coefficient bearing on H1–H3  
 793 into a single view. Panel A shows the credit-access effect (H1): every point  
 794 estimate is positive and every confidence interval excludes zero, in both sam-

Table 10: Global-sample regressions (dependent variable: CO2-emissions monitoring, binary). Country-clustered standard errors in parentheses; M2's SBFN and regulatory-quality main effects are absorbed by country fixed effects and are not separately estimable.

|                              | M1: no country FE   | M2: country FE      |
|------------------------------|---------------------|---------------------|

| Countries                    | 159                 | 159                 |

\*\*\*  $p < 0.01$ , \*\*  $p < 0.05$ , \*  $p < 0.10$ . Taiwan dropped (no WGI coverage).

Figure 3. Combined sample coverage: 166 economies (41 primary rich-module + 162 global minimal-indicator, net of overlap)

Figure 3: Combined sample coverage: 166 economies (41 primary + 162 global, net of overlap), shaded by SBFN status.

795 ples and all four estimators. Panels B and C show the credit  $\times$  SBFN and  
796 credit  $\times$  regulatory-quality interactions (H2, H3): every single confidence in-  
797 terval, across both samples and every estimator, straddles zero. Figure 5  
798 shows the same non-result from a completely different angle—the causal  
799 forest’s conditional average treatment effects broken out by SBFN status,  
800 regulatory-quality tercile, and firm-size category all overlap both each other  
801 and the overall average treatment effect. No subgroup split, by any variable  
802 examined in this paper, recovers a distinguishable effect.

## 803 6. Discussion

804 Put in plain economic terms, the paper’s central finding is this: a firm  
805 holding a bank credit line is associated with an adoption probability roughly  
806 13 percentage points higher than an otherwise-similar firm without one—

Figure 4: Coefficient estimates across every specification and both samples.

Figure 5: Causal forest conditional average treatment effects, by subgroup.

807 an association net of the observed firm and country controls, not a causally  
808 identified effect, for the reasons given in Limitation 1 below—comparable in  
809 magnitude to the gap between a small firm and a large one—and that gap is  
810 essentially the same size whether the firm sits in an SBFN sustainable-finance  
811 policy adopter or a non-adopter, and essentially the same size whether the  
812 country’s regulatory quality sits in the bottom, middle, or top third of the  
813 sample (Figure 4). Firms in SBFN-adopting economies are, on average, some  
814 15–20 percentage points *less* likely to have adopted a green practice at all—a  
815 level gap, not a slope gap.

816 This convergence matters most because of how differently the two sam-  
817 ples could have failed to agree. The primary and global samples share al-  
818 most no economies in common, were fielded in different half-decades, measure  
819 green practice adoption with entirely different survey items, and reach insti-  
820 tutional settings—high-income, non-SBFN economies such as Australia and  
821 Germany—that the primary sample cannot touch at all. A finding that held  
822 only in the 41-country ECA-MENA sample could plausibly be a regional or  
823 period-specific artefact; a finding that survives unchanged when re-estimated  
824 on 162 largely non-overlapping economies under a sharper identification strat-  
825 egy is considerably harder to explain away as such.

826 This is worth dwelling on precisely because it complicates rather than  
827 confirms the implicit premise of much of the existing green-credit-policy lit-  
828 erature, which is disproportionately built on evidence from China’s unusu-  
829 ally mature, unusually well-resourced green credit guidelines (Li et al., 2023;  
830 Huang et al., 2023; Dai et al., 2025). Our sample includes economies at ev-  
831 ery stage of the SBFN’s own progression framework—from Jordan and the

832 Kyrgyz Republic’s initial “Commitment” stage to Mongolia’s “Advancing” im-  
 833 plementation a full seven years after founding membership—and across that  
 834 entire range, we find no evidence that formal policy adoption changes how a  
 835 firm’s credit access translates into green investment behaviour. Section 5.4’s  
 836 most novel result gives one plausible redirection of the question, though not  
 837 a tidy answer to it: the heterogeneity that *does* exist in the credit-green  
 838 relationship is overwhelmingly a firm-size phenomenon (75.6% of explained  
 839 variance) rather than a country-institutional one (regulatory quality 19.9%,  
 840 SBFN status a mere 2.6%)—yet, as Section 5.4 reports honestly, collaps-  
 841 ing this into the Surveys’ own coarse Small/Medium/Large strata does not  
 842 recover a clean gradient in either direction, so we cannot yet say whether  
 843 it is small or large firms for whom the credit-green channel runs stronger,  
 844 only that firm scale—in some more granular or non-monotonic form than a  
 845 three-category split reveals—is where the forest locates most of the effect het-  
 846 erogeneity a country-level policy variable does not. What this does support is  
 847 a reorientation of where policy attention belongs: if the operative constraint  
 848 sits at the level of which individual firms can absorb a green investment’s  
 849 fixed costs once financed, rather than at the level of whether a supervisory  
 850 guideline nudges banks to lend more broadly, then a country-level supervisory  
 851 mandate operating on the extensive margin of bank lending decisions may be  
 852 aimed at the wrong margin regardless of its own institutional credibility—a  
 853 question future work with a finer-grained firm-size or capacity measure is  
 854 better placed to resolve than the coarse categories available here.

855 It is worth being precise about what this null does and does not establish.  
 856 “No interaction detected” and “no institutional complementarity exists” are

not the same claim, and we do not want the paper’s repeated confirmation of the former to be read as having settled the latter. At least three distinct readings remain open. First, our preferred reading throughout the paper: the complementarity genuinely does not operate through this channel. Second, a linear interaction term may simply be the wrong functional form to detect a genuinely threshold-shaped complementarity—SBFN’s own Multi-Tiered Progress Framework (Section 2) treats policy adoption as a graded process from an initial “Commitment” stage through “Consolidating,” and our binary membership coding (Limitation 2 below) could easily average over a complementarity that only activates once a jurisdiction clears a particular progression stage, in a way four estimators built around a single membership dummy cannot recover. Third, the Worldwide Governance Indicators’ broad, economy-wide regulatory-quality measure may simply not proxy the specific banking-supervisory capacity a green-lending guideline actually depends on (Limitation 5); a null on this proxy is evidence about the proxy’s channel, not necessarily about supervisory capacity in general. We think the first reading is the best-supported of the three given the evidence in Section 5, but we hold it as the best current account rather than as a claim the paper has definitively ruled the other two out.

A further alternative worth engaging directly, since it is the more theoretically interesting institutional-mechanism story a system-change-oriented reading of our results would want addressed: SBFN guidelines could, in principle, be working exactly as intended on the *extensive* margin of who obtains credit at all, rather than on the *intensive* margin our interaction terms test. If a green-banking guideline induces banks in adopting jurisdictions to extend

882 credit more broadly to environmentally promising firms that would otherwise  
883 have gone unfinanced, that effect shows up as a shift in *which* firms hold a  
884 credit line, not as a different adoption gap between financed and unfinanced  
885 firms conditional on already holding one—exactly the quantity our credit  $\times$   
886 SBFN interaction estimates. Testing this directly would require modelling  
887 credit access itself, rather than green adoption conditional on credit access,  
888 as a function of SBFN status and firm environmental characteristics; our  
889 design, built around the demand-side finance-to-green channel, does not do  
890 this, and we flag it explicitly as an unaddressed alternative mechanism rather  
891 than one our null result rules out.

892 We should also be candid about a limit of our outcome measure itself.  
893 Every green-practice-adoption item in this paper is firm-reported, and we  
894 cannot rule out that self-reported adoption rates differ systematically from  
895 banks’ own compliance reporting to their SBFN supervisor in ways our  
896 data cannot observe—a general concern about compliance-reporting-versus-  
897 practice gaps that applies to any policy evaluated through the regulated  
898 party’s own attestations, and one a firm-level survey instrument, however  
899 carefully harmonized, cannot fully resolve on its own.

900 To our knowledge, this paper is also the first to test the SBFN frame-  
901 work’s own theory of change against firm-level, rather than bank-level or  
902 policy-stage, outcomes: the network’s periodic Global Progress Reports (Sec-  
903 tion 2) measure and publicize each member jurisdiction’s regulatory-output  
904 stage, but not whether that output changes what happens on the ground  
905 for the firms the policy ultimately targets. Read this way, our null result is  
906 directly relevant to the SBFN’s and the IFC’s own self-evaluation practice, in-

907 dependent of what it implies for the academic institutional-complementarity  
908 literature: a framework can progress steadily through Commitment, Develop-  
909 ing, and Advancing stages by every measure the network itself tracks, while  
910 the firm-level channel that is its ultimate point remains, on this evidence,  
911 unmoved.

912     The one interaction that does clear a conventional significance threshold—  
913 a *negative* credit  $\times$  SBFN effect when finance access is measured through  
914 overdraft facilities rather than term credit lines (Section 5)—is, we think,  
915 more consistent with this redirection than with a simple failure of green  
916 banking policy. Overdrafts finance working capital, not the kind of multi-year  
917 capital expenditure our outcome variable measures; if SBFN-guided lending  
918 is disproportionately channelled through the term-loan instruments better  
919 suited to financing a solar installation or an energy-efficiency retrofit, exactly  
920 the pattern we find—a null-to-positive effect on credit lines, a negative one  
921 on overdrafts—is what a supervisor successfully steering credit toward long-  
922 horizon green investment, rather than short-horizon working capital, would  
923 produce. We flag this as suggestive rather than established, since it is a  
924 single significant coefficient among the many interaction tests reported across  
925 Tables 3–9—and, as Section 5 reports formally (Table 8), it does not survive a  
926 Benjamini–Hochberg correction for multiple comparisons at any conventional  
927 false discovery rate—and our data cannot directly verify the underlying loan-  
928 tenor mechanism.

929     Read against this special issue’s organizing themes of state capacity and  
930 policy credibility, our results sit closer to a state-capacity-is-necessary-but-  
931 firm-level-frictions-bind-independently story than to a straightforward institutional-

932 complementarity one in which stronger regulatory quality unlocks a latent  
933 policy effect that would otherwise lie dormant. Regulatory quality matters—  
934 it raises the general baseline propensity to adopt green practices regardless of  
935 a firm’s own financing arrangement—but it does not appear to be the miss-  
936 ing ingredient that would let a green banking guideline reshape the credit-  
937 to-green channel specifically. This suggests, tentatively, that the binding  
938 constraint on green credit policy’s effectiveness in our sample is less about  
939 whether the supervising jurisdiction has the state capacity to make the guide-  
940 line credible, and more about whether firms below a certain scale can absorb  
941 a green investment’s fixed costs at all once credit is available—a question  
942 about firm-level absorptive capacity that sits one level down from the state-  
943 capacity question the SBFN framework itself is designed to address.

## 944 **7. Conclusion**

945 This paper set out to test whether the wave of green banking policy  
946 adoption coordinated through the Sustainable Banking and Finance Network  
947 changes the relationship between firm-level access to finance and green invest-  
948 ment behaviour, and whether any such moderation depends on the regulatory  
949 capacity available to make the underlying policy credible. Using harmonized  
950 World Bank Enterprise Survey data spanning 41 economies’ full 2018–2020  
951 Green Economy Module rollout, a four-country waste-minimization supple-  
952 mentary check, and an independently assembled 162-economy global sample  
953 spanning 2021–2026 and reaching for the first time into high-income, non-  
954 SBFN economies, we apply a deliberately escalating sequence of estimators—  
955 a classical benchmark chosen to expose its own limitation, a Bayesian hier-

956 archical model built to give the moderation hypothesis a fair test, a causal  
957 forest imposing no functional-form assumption at all, and, on the global  
958 sample specifically, a country-fixed-effects specification the primary sample's  
959 single wave cannot support—and find four consistent results. First, access  
960 to bank credit is robustly associated with a firm's green practice adoption,  
961 a relationship that survives every specification, subsample, and alternative-  
962 outcome check in the paper and replicates independently in both the small  
963 waste-minimization sample and the full 162-economy global sample. Second,  
964 neither SBFN policy adoption nor regulatory quality moderates that rela-  
965 tionship in any of the four estimators, on either sample, though both shift  
966 the general level of green adoption directly and substantially in the primary  
967 sample. Third, where genuine effect heterogeneity does exist, it is concen-  
968 trated at the level of firm size rather than country institutions. Fourth, and  
969 most importantly for the paper's overall credibility, this entire pattern repli-  
970 cates on a sample sharing almost no economies with the primary one, fielded  
971 years later, measured with a different outcome item, and identified under a  
972 materially sharper econometric strategy—the single strongest piece of evi-  
973 dence in the paper that the null on institutional moderation is a real feature  
974 of the data rather than an artefact of any one sample, period, or estimator.

975 For policy, the implication is not that green banking guidelines are inef-  
976 fective, but that our evidence does not support treating them as an effective  
977 lever specifically for widening the gap in green investment between financed  
978 and unfunded firms—the margin most green-credit-policy literature implic-  
979 itly assumes they operate on. If our tentative loan-tenor interpretation of  
980 the overdraft-interaction finding is correct, policymakers designing or refining

981 SBFN-style frameworks may find more traction focusing supervisory atten-  
982 tion on the term-lending instruments that actually finance green capital ex-  
983 penditure, and on complementary measures—technical assistance, matching  
984 grants, or credit guarantees—that address smaller firms’ absorptive-capacity  
985 constraints directly, rather than assuming that a bank-level supervisory man-  
986 date alone will reach firms regardless of scale.

987     We close with six limitations that bound how far these conclusions travel.  
988 First, both samples are single cross-sections per country (Section 4 discusses  
989 why a genuine panel on this outcome, and the staggered-adoption design it  
990 would support, does not exist in the published WBES data): they cannot  
991 rule out reverse causality (firms already predisposed to green investment may  
992 find it easier to obtain credit) or unobserved, time-invariant country charac-  
993 teristics correlated with both SBFN adoption and the baseline propensity to  
994 adopt green practices, and our identification rests on firm-level variation in  
995 credit access interacting with a plausibly firm-exogenous country-level policy  
996 indicator, not a natural experiment; the global sample’s country fixed effects  
997 sharpen this only for the interaction terms, not for the credit main effect  
998 itself. Second, SBFN membership is a binary proxy for what the network’s  
999 own multi-tiered progression framework treats as a genuinely graded pro-  
1000 cess; a natural extension would model policy stage—Commitment through  
1001 Consolidating—as an ordinal or continuous treatment rather than collapsing  
1002 it to membership status, which our binary coding necessarily does, and which  
1003 for the global sample’s regional entries (the CEMAC and Eastern Caribbean  
1004 groupings, Section 4) additionally rests on an inference about which specific  
1005 economies a regional listing covers rather than an explicit per-country state-

1006 ment. Third, the four-economy waste-minimization check cannot re-test the  
1007 SBFN contrast itself, since three of its four economies are SBFN members,  
1008 and combines non-identical outcome items across countries by construction  
1009 of the WBES's own shortened, randomized module design in later survey  
1010 waves—a genuine data-availability constraint rather than a methodological  
1011 choice. Fourth, the global sample's CO2-monitoring outcome is a single item  
1012 rather than the primary sample's seven-item composite, and is a narrower  
1013 construct than "green practice adoption" in the sense the primary sample  
1014 measures it; that the same qualitative pattern holds on this narrower mea-  
1015 sure is reassuring but does not establish that it would hold on a richer one,  
1016 were a richer one available at global scale. Fifth, the Worldwide Gover-  
1017 nance Indicators' regulatory-quality measure is a broad, economy-wide gov-  
1018 ernance indicator rather than a banking-supervision-specific capacity mea-  
1019 sure; a supervisor-specific index, were one available consistently across this  
1020 country set, would sharpen the institutional-complementarity test consider-  
1021 ably. Sixth, our design tests only the intensive margin of the credit-to-green  
1022 channel (the adoption gap between financed and unfinanced firms); it cannot  
1023 rule out that SBFN policy operates instead on the extensive margin of which  
1024 firms obtain credit in the first place, nor can our firm-reported outcome  
1025 measure distinguish actual practice adoption from a compliance-reporting  
1026 gap between what firms report and what banks report to their supervisor  
1027 (Section 6). We leave each of these to future work.

1028 **Declaration of generative AI and AI-assisted technologies in the**  
1029 **manuscript preparation process**

1030 During the preparation of this work the author(s) used Claude (An-  
1031 thropic) to assist with data extraction and cleaning from World Bank Enter-  
1032 prise Surveys microdata (including identification and extraction of the stan-  
1033 dardized cross-country database underlying the global sample), construction  
1034 of the analysis datasets and merge with country-level SBFN and Worldwide  
1035 Governance Indicators data, execution of the statistical and machine-learning  
1036 analyses reported in Section 5, generation of Figures 1–3, and drafting of por-  
1037 tions of the manuscript text. After using this tool, the author(s) reviewed  
1038 and edited the content as needed and take full responsibility for the content  
1039 of the published article.

1040 **Appendix A. SBFN policy status and regulatory quality, full sam-**  
1041 **ple**

1042 Table A.11 reports, for all 47 economy-years in the paper’s primary and  
1043 small-sample supplementary check, the SBFN membership status coded for  
1044 the analysis, the join year where applicable, the SBFN Multi-Tiered Progress  
1045 Framework stage in force nearest the survey year, and the exact year of the  
1046 Worldwide Governance Indicators observation used. Full per-country source  
1047 citations (the specific SBFN Global Progress Report, country addendum, or  
1048 accession announcement consulted for every determination) are available in  
1049 the online supplementary material. The analogous 162-economy table for  
1050 the global sample (Section 4) is summarized by region in Appendix C and

1051 provided in full in the online supplementary material and the replication  
1052 package.

Table A.11: SBFN policy status and regulatory quality, full 47-  
economy sample.

| Economy                           | SBFN member | Join year | Stage at survey                  | WGI year |

## 1053 Appendix B. Bayesian model convergence diagnostics

1054 Convergence diagnostics for every focal parameter of the hierarchical  
1055 model reported in Table 4 are included directly in that table ( $\hat{R}$  column); the  
1056 full posterior summary also includes  $\text{ess}_{\text{bulk}}$  ranging from 797 (SBFN member)  
1057 to 2,270 (credit  $\times$  regulatory quality), comfortably above the conventional  
1058 minimum threshold of 400 effective samples per parameter for stable poste-  
1059 rior summaries at four chains. No divergent transitions were flagged during  
1060 sampling (NUTS via the nutpie sampler, four chains of 1,000 post-warmup

1061 draws each after 1,000 tuning iterations).

## 1062 **Appendix C. Global-sample SBFN status, regional summary**

1063 Of the 162 global-sample economy-years, 61 are coded as SBFN members  
1064 as of their survey year and 101 as non-members. Table C.12 reports the  
1065 regional distribution of the 61 members, drawn from the SBFN data por-  
1066 tal’s regional classification; five of the 61 (Peru, Philippines, Timor-Leste,  
1067 Bangladesh, and Indonesia) carry the deeper per-country sourcing already  
1068 reported in Appendix A, having been determined during the primary sam-  
1069 ple’s original research pass rather than from the portal roster alone.

Table C.12: Global-sample SBFN members, by SBFN region.

| Region                       | Member economy-years |
|------------------------------|----------------------|
| Latin America and Caribbean  | 17                   |
| Africa                       | 12                   |
| Europe and Central Asia      | 11                   |
| East Asia and Pacific        | 11                   |
| South Asia                   | 6                    |
| Middle East and North Africa | 4                    |
| Total                        | 61                   |

## 1070 **Additional material**

### 1071 *Online appendix*

1072 Appendix A, Appendix B, and Appendix C appear above; per-country  
1073 source citations at the level of detail compiled during data construction (in-

1074 individual SBFN Global Progress Report page references, country-addendum  
1075 URLs, and IFC accession-announcement links for every non-obvious deter-  
1076 mination in the primary sample; the full 162-row global-sample SBFN/WGI  
1077 table underlying Appendix C) are available in the online supplementary  
1078 material accompanying this submission.

### 1079 *Data availability*

1080 Data in support of the findings of this study is available from the cor-  
1081 responding author upon reasonable request, subject to the World Bank En-  
1082 terprise Surveys' own terms of use for the underlying firm-level microdata  
1083 (enterprisesurveys.org, free registration required), including the standard-  
1084 ized cross-country database and Productivity Database underlying the global  
1085 sample. The country-level SBFN policy-status (including the SBFN data  
1086 portal's member roster underlying the global sample) and Worldwide Gover-  
1087 nance Indicators datasets constructed for this paper, together with the full  
1088 analysis and replication code, are available in a public GitHub repository;  
1089 the repository link is withheld from this anonymized manuscript, and repos-  
1090 itory access is restricted for the duration of double-anonymized review, to  
1091 avoid identifying the authors to reviewers. The link will be provided to the  
1092 editor upon submission and made publicly accessible again to readers upon  
1093 acceptance.
